

Geometric Registration for Deformable Shapes

3.1 Introduction to geometric key point detection and feature descriptors

What is Global Matching? · Feature Descriptors

The story so far

Problem statement

- Given pair of shapes/scans, produce an alignment

Local registration

- Solves for an alignment assuming that pose is similar or motion is small between shapes / scans
- Like “tracking” of motion in this respect

In this session: Global matching

What is Global Matching?

Problem statement

- Find the globally optimal alignment between a pair of shapes
- Search space = set of all possible correspondences
- Same sense as local minimum vs global minimum in optimization

- Don't get confused with **global registration**
 - “Global registration” is commonly used to refer to aligning *multiple scans* together to make a single shape

Local vs Global

Local Matching

- Search in space of *transformations*, minimize alignment energy
- Relatively small search space... relatively easy

vs.

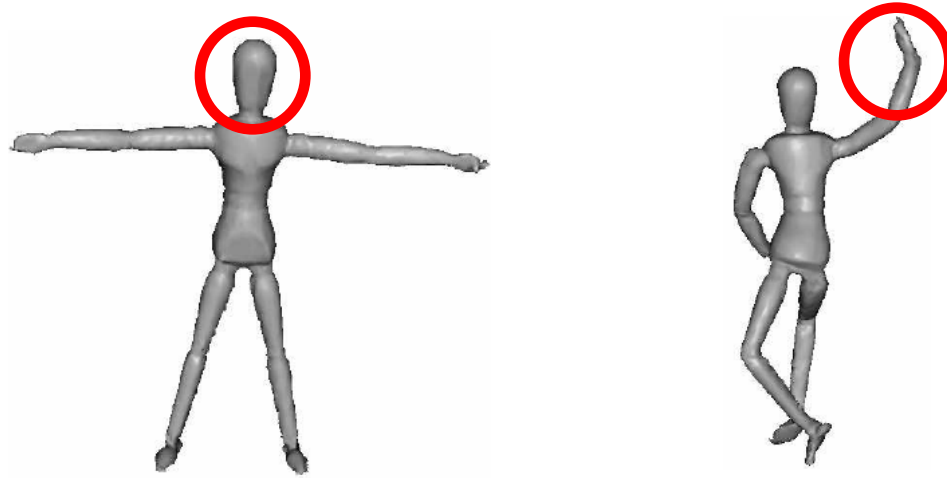

Global Matching

- Search in the space of *all possible correspondences*, minimize alignment energy
- Incredibly large search space... nearly impossible?

➔ **Features to the rescue!**

Our eyes recognize features

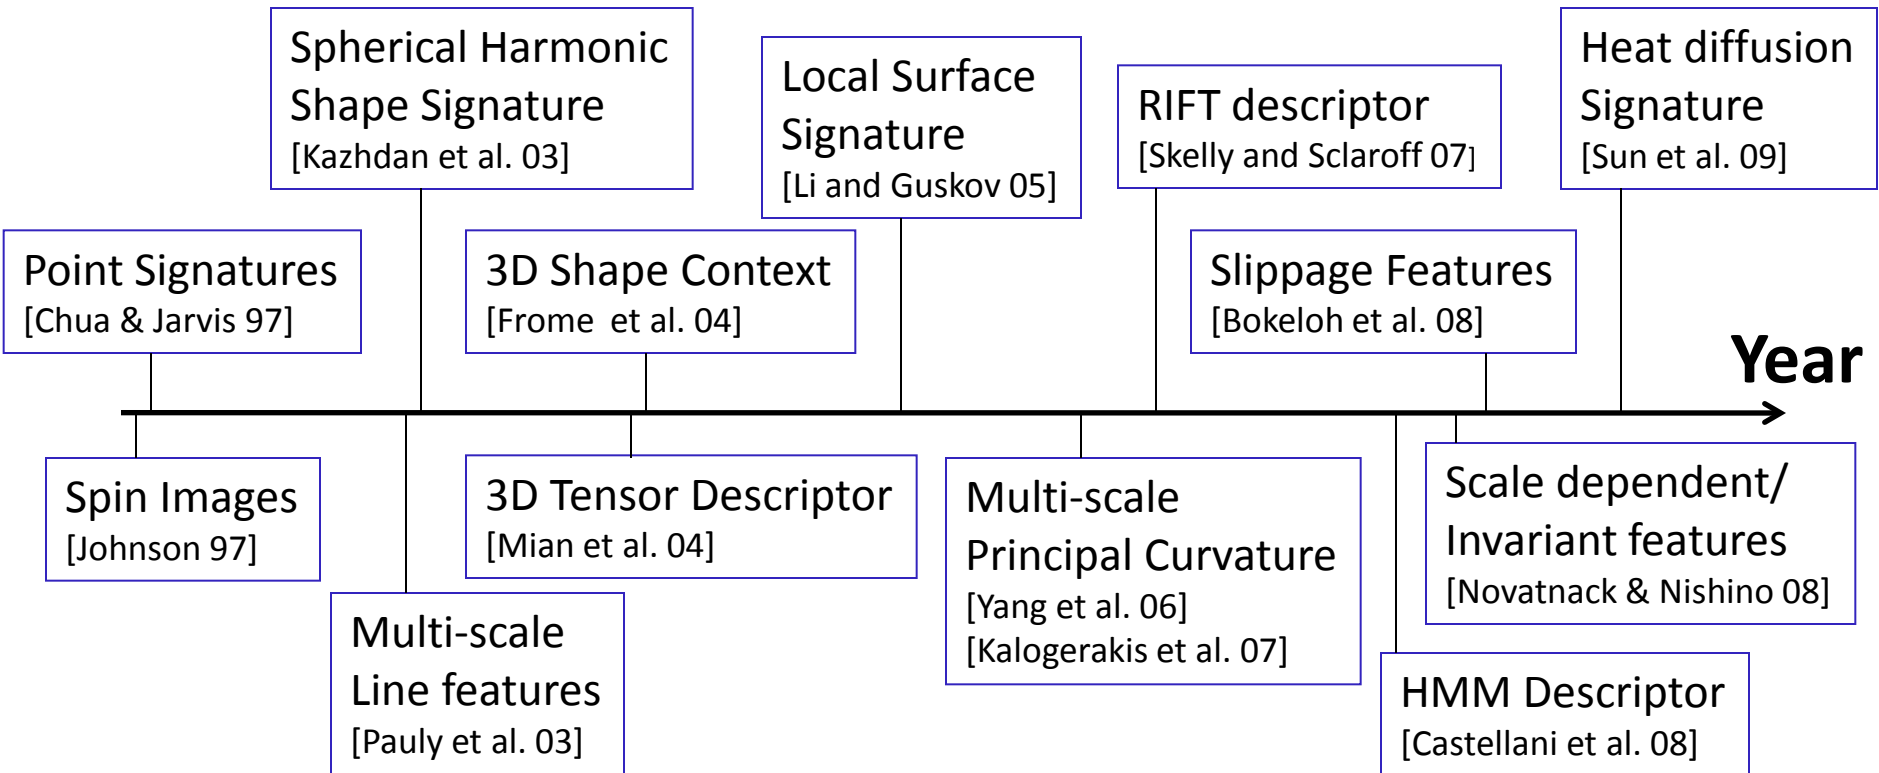

Face \neq Arm

- Why? It looks different!
- Can dramatically reduce space of possible solutions
- How can we directly compare the geometric content to recognize similarity/dissimilarity?

Types of features

Welcome to the world of feature descriptors..

- Many more exist... possibly with different objectives
 - ex) Matching whole shape vs. local patches

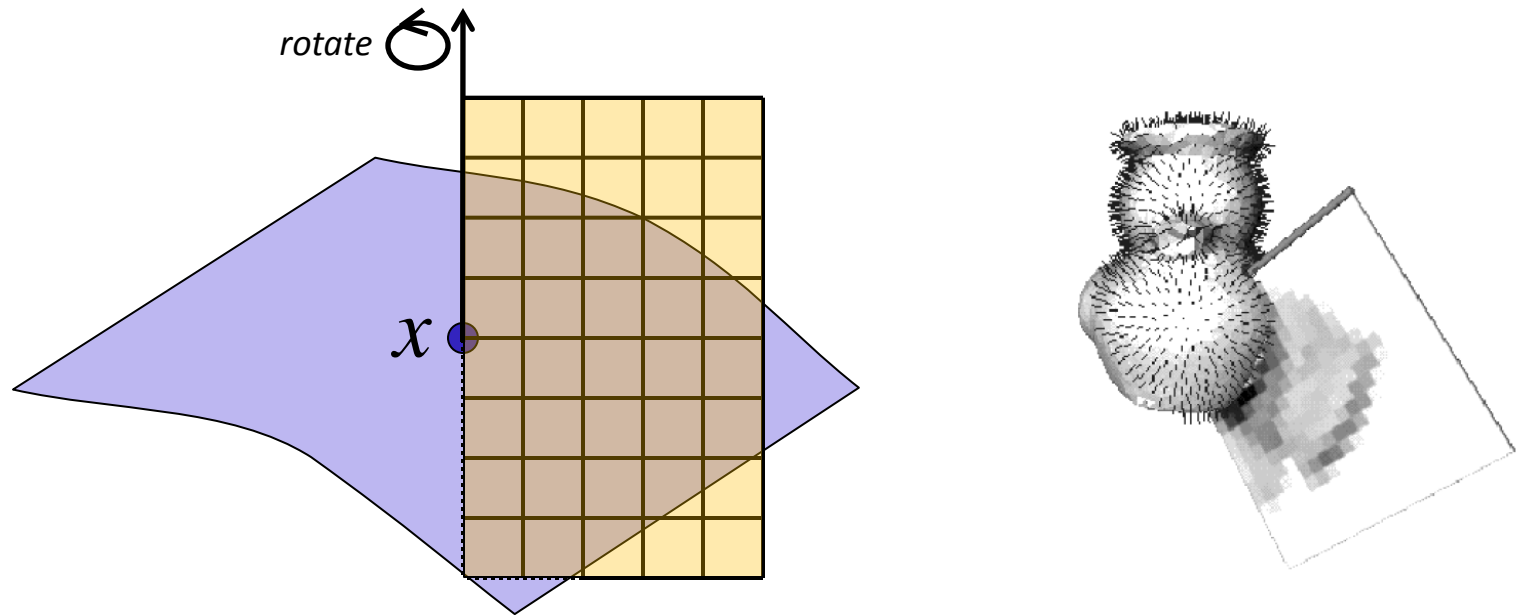

An Example: Spin Images

One of the earliest feature descriptors

- Established, simple, well analyzed
- Clearly illustrates the process of how this type of recognition works
- Also illustrates potential problems & drawbacks common to any type of feature descriptor

Spin Image Construction

- Converts a local patch of geometry into an image, which we can directly compare to determine similarity

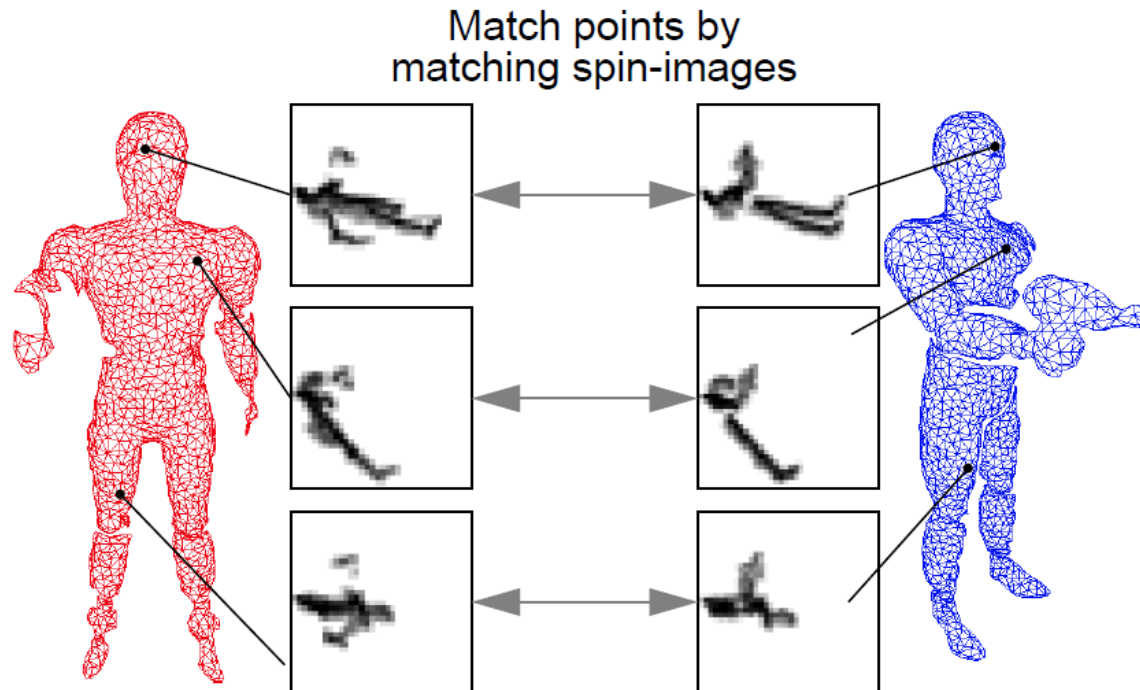

Images from [Johnson 97]

Spin Image Matching

Compare images directly to obtain similarity score

- Linear correlation coefficient \rightarrow Similarity measure
- Compute only in “overlap”: when both bins have a value

Images from [Johnson 97]

Compressing Spin Images

Spin images from the same model are similar

- Reduce redundancy with PCA compression
- Save space and matching time

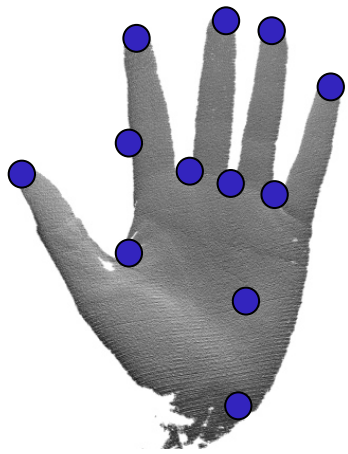

Images from [Johnson 97]

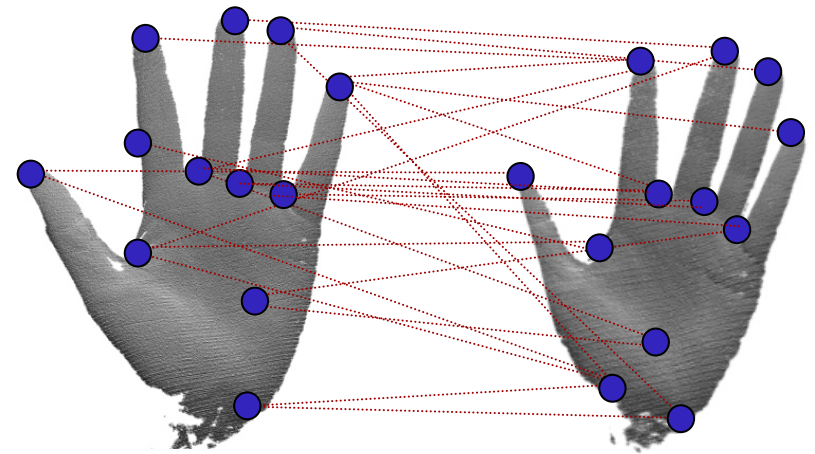

Spin Image Matching

Can detect geometrically similar parts

- But there are limitations

Detected feature points

Matched points

Problem #1: False positive/negative

False positive

- Saying that two points match when in fact they don't

False negative

- Saying that two points don't match when in fact they do

Aka “noise” or “outliers”

- Occurs with any type of descriptor

Problem #2: Parameter Selection

Examples of parameters in spin images

- Bin size
- Image width
- Support angle
- Mesh resolution

How to pick the best parameters?

- Fortunately well analyzed for spin images
- Others are studied/analyzed to varying degrees

Problem #3: Non-unique patches

What to do in flat/spherical/cylindrical regions?

- In this case, the region is not “unique” or distinctive
- Doesn't make sense to compare such regions..
- Or does it?
 - Increasing the scale/support
- Multi-scale features, select scale automatically
- “Global” features – ex) heat diffusion signature

Conclusion

Feature descriptors

- Very useful for narrowing down search space
- Does not solve the problem completely
- Additional optimization in the (reduced) search space is needed → explored in the next few talks!
