Runtime Verification

Definition (Runtime Verification)

Runtime verification is the discipline of computer science that deals with the study, development, and application of those verification techniques that allow checking whether a *run* of a system under scrutiny (SUS) satisfies or violates a given correctness property.

Its distinguishing research effort lies in *synthesizing monitors from high level specifications*.

Runtime Verification

Definition (Runtime Verification)

Runtime verification is the discipline of computer science that deals with the study, development, and application of those verification techniques that allow checking whether a *run* of a system under scrutiny (SUS) satisfies or violates a given correctness property.

Its distinguishing research effort lies in *synthesizing monitors from high level specifications*.

Definition (Monitor)

A **monitor** is a device that reads a finite trace and yields a certain **verdict**.

A verdict is typically a truth value from some truth domain.

Linear-time Temporal Logic (LTL)

Semantics

over $w \in (2^{AP})^\omega = \Sigma^\omega$

Abbreviation

$F\varphi \equiv \text{true}U\varphi$ $G\varphi \equiv \neg F\neg\varphi$

Example

$G\neg(\text{critic}_1 \wedge \text{critic}_2), G(\neg\text{alive} \rightarrow X\text{alive})$

LTL on infinite words

Definition (LTL semantics (traditional))

Semantics of LTL formulae over an infinite word $w = a_0a_1 \dots \in \Sigma^\omega$, where

$$w^i = a_i a_{i+1} \dots$$

$$w \models \text{true}$$

$$w \models p \quad \text{if } p \in a_0$$

$$w \models \neg p \quad \text{if } p \notin a_0$$

$$w \models \neg \varphi \quad \text{if not } w \models \varphi$$

$$w \models \varphi \vee \psi \quad \text{if } w \models \varphi \text{ or } w \models \psi$$

$$w \models \varphi \wedge \psi \quad \text{if } w \models \varphi \text{ and } w \models \psi$$

$$w \models X\varphi \quad \text{if } w^1 \models \varphi$$

$$w \models \bar{X}\varphi \quad \text{if } w^1 \not\models \varphi$$

$$w \models \varphi U \psi \quad \text{if there is } k \text{ with } 0 \leq k < |w|: w^k \models \psi$$

and for all l with $0 \leq l < k$ $w^l \not\models \varphi$

$$w \models \varphi R \psi \quad \text{if for all } k \text{ with } 0 \leq k < |w|: (w^k \models \psi$$

or there is l with $0 \leq l < k$ $w^l \models \varphi$)

SALT - Smart Assertion Language for Temporal Logic

SALT

Goal

Do you want to specify the behavior of your program in a rigorously yet comfortable manner?
Do you see the benefits of temporal specifications but are bothered by the awkward formalisms available?
Do you want to use

- the power of a *Model Checker* to improve the quality of your systems or
- the powerful *runtime reflection* approach for bug hunting and elimination

Runtime Verification for LTL

Idea

Specify correctness properties in LTL

Definition (Syntax of LTL formulae)

Let p be an atomic proposition from a finite set of atomic propositions AP .
The set of LTL formulae, denoted with LTL , is inductively defined by the following grammar:

$$\begin{aligned} \varphi ::= & \text{true} \mid p \mid \varphi \vee \varphi \mid \varphi \mathbf{U} \varphi \mid \mathbf{X}\varphi \mid \\ & \text{false} \mid \neg p \mid \varphi \wedge \varphi \mid \varphi \mathbf{R} \varphi \mid \bar{\mathbf{X}}\varphi \mid \\ & \neg\varphi \end{aligned}$$

Truth Domains

Lattice

- ▶ A **lattice** is a partially ordered set $(\mathcal{L}, \sqsubseteq)$ where for each $x, y \in \mathcal{L}$, there exists
 1. a unique **greatest lower bound** (glb), which is called the **meet** of x and y , and is denoted with $x \sqcap y$, and
 2. a unique **least upper bound** (lub), which is called the **join** of x and y , and is denoted with $x \sqcup y$.
- ▶ A lattice is called **finite** iff \mathcal{L} is finite.
- ▶ Every finite lattice has a well-defined unique least element, called **bottom**, denoted with \perp ,
- ▶ and analogously a greatest element, called **top**, denoted with \top .

Truth Domains (cont.)

Lattice (cont.)

- ▶ A lattice is **distributive**, iff $x \sqcap (y \sqcup z) = (x \sqcap y) \sqcup (x \sqcap z)$, and, dually, $x \sqcup (y \sqcap z) = (x \sqcup y) \sqcap (x \sqcup z)$.
- ▶ In a **de Morgan** lattice, every element x has a unique **dual** element \bar{x} , such that $\bar{\bar{x}} = x$ and $x \sqsubseteq y$ implies $\bar{y} \sqsubseteq \bar{x}$.

Definition (Truth domain)

We call \mathcal{L} a **truth domain**, if it is a finite distributive de Morgan lattice.

LTl's semantics using truth domains

Definition (LTl semantics (common part))

Semantics of LTl formulae over a finite or infinite word $w = a_0 a_1 \dots \in \Sigma^\infty$

Boolean constants

$$[w \models \text{true}]_\Sigma = \top$$

$$[w \models \text{false}]_\Sigma = \perp$$

Boolean combinations

$$[w \models \neg \varphi]_\Sigma = \overline{[w \models \varphi]_\Sigma}$$

$$[w \models \varphi \vee \psi]_\Sigma = [w \models \varphi]_\Sigma \sqcup [w \models \psi]_\Sigma$$

$$[w \models \varphi \wedge \psi]_\Sigma = [w \models \varphi]_\Sigma \sqcap [w \models \psi]_\Sigma$$

atomic propositions

$$[w \models p]_\Sigma = \begin{cases} \top & \text{if } p \in a_0 \\ \perp & \text{if } p \notin a_0 \end{cases}$$

$$[w \models \neg p]_\Sigma = \begin{cases} \top & \text{if } p \notin a_0 \\ \perp & \text{if } p \in a_0 \end{cases}$$

next X/weak next X **TBD**

until/release

$$[w \models \varphi U \psi]_\Sigma = \begin{cases} \top & \text{there is a } k, 0 \leq k < |w| : [w^k \models \psi]_\Sigma = \top \text{ and} \\ & \text{for all } l \text{ with } 0 \leq l < k : [w^l \models \varphi]_\Sigma = \top \\ \text{TBD} & \text{else} \end{cases}$$

$$\varphi R \psi \equiv \neg(\neg \varphi U \neg \psi)$$

LTL on finite, but not completed words

Application area: Specify properties of finite but expanding word

LTL on finite, but not completed words

Be Impartial!

- ▶ go for a final verdict (\top or \perp) only if you really know

LTL on finite, but not completed words

Be Impartial!

- ▶ go for a final verdict (\top or \perp) only if you really know
- ▶ *stick to your word*

LTL on finite, but not complete words

Impartiality implies multiple values

Every two-valued logic is not impartial.

Definition (FLTL₄)

Semantics of FLTL formulae over a word $u = a_0 \dots a_{n-1} \in \Sigma^*$

next

$$[u \models X\varphi]_4 = \begin{cases} [u^1 \models \varphi]_4 & \text{if } u^1 \neq \epsilon \\ \perp^p & \text{otherwise} \end{cases}$$

weak next

$$[u \models \bar{X}\varphi]_4 = \begin{cases} [u^1 \models \varphi]_4 & \text{if } u^1 \neq \epsilon \\ \top^p & \text{otherwise} \end{cases}$$

Monitoring LTL on finite but expanding words

Left-to-right!

Monitoring LTL on finite but expanding words

Rewriting

Idea: Use rewriting of formula

Evaluating FLTL4 for each subsequent letter

- ▶ evaluate atomic propositions
- ▶ evaluate next-formulas
- ▶ that's it thanks to

$$\varphi U \psi \equiv \psi \vee (\varphi \wedge X\varphi U \psi)$$

and

$$\varphi R \psi \equiv \psi \wedge (\varphi \vee \bar{X}\varphi R \psi)$$

- ▶ and remember what to evaluate for the next letter

Evaluating FLTL4 for each subsequent letter

Pseudo Code

```

evalFLTL4 true    a = (⊤, ⊤)
evalFLTL4 false  a = (⊥, ⊥)
evalFLTL4 p      a = ((p in a), (p in a))
evalFLTL4 ¬φ     a = let (valPhi, phiRew) = evalFLTL4 φ a
                  in (valPhi, ¬phiRew)
evalFLTL4 φ ∨ ψ  a = let
                  (valPhi, phiRew) = evalFLTL4 φ a
                  (valPsi, psiRew) = evalFLTL4 ψ a
                  in (valPhi ⊔ valPsi, phiRew ∨ psiRew)
evalFLTL4 φ ∧ ψ  a = let
                  (valPhi, phiRew) = evalFLTL4 φ a
                  (valPsi, psiRew) = evalFLTL4 ψ a
                  in (valPhi ⊓ valPsi, phiRew ∧ psiRew)
evalFLTL4 φ U ψ  a = evalFLTL4 ψ ∨ (φ ∧ X(φ U ψ)) a
evalFLTL4 φ R ψ  a = evalFLTL4 ψ ∧ (φ ∨ X̄(φ R ψ)) a
evalFLTL4 Xφ     a = (⊥p, φ)
evalFLTL4 X̄φ     a = (⊤p, φ)
    
```

Monitoring LTL on finite but expanding words

Automata-theoretic approach

- ▶ Synthesize automaton
- ▶ Monitoring = stepping through automaton

Rewriting vs. automata

Rewriting function defines transition function

```

evalFLTL4 true  a = (⊤, true)
evalFLTL4 false a = (⊥, false)
evalFLTL4 p     a = ((p in a), (p in a) ? true : false)
evalFLTL4 ¬φ    a = let (valPhi, phiRew) = evalFLTL4 φ a
                  in (valPhi, ¬phiRew)
evalFLTL4 φ ∨ ψ a = let
                  (valPhi, phiRew) = evalFLTL4 φ a
                  (valPsi, psiRew) = evalFLTL4 ψ a
                  in (valPhi ⊔ valPsi, phiRew ∨ psiRew)
evalFLTL4 φ ∧ ψ a = let
                  (valPhi, phiRew) = evalFLTL4 φ a
                  (valPsi, psiRew) = evalFLTL4 ψ a
                  in (valPhi ⊓ valPsi, phiRew ∧ psiRew)
evalFLTL4 φ U ψ a = evalFLTL4 ψ ∨ (φ ∧ X(φ U ψ)) a
evalFLTL4 φ R ψ a = evalFLTL4 ψ ∧ (φ ∨ X̄(φ R ψ)) a
evalFLTL4 Xφ    a = (⊥p, φ)
evalFLTL4 X̄φ    a = (⊤p, φ)
  
```

Supporting alternating finite-state machines

Definition (Alternating Mealy Machine)

A **alternating Mealy machine** is a tuple $\mathcal{M} = (Q, \Sigma, \Gamma, q_0, \delta)$ where

- ▶ Q is a finite set of **states**,
- ▶ Σ is the **input alphabet**,
- ▶ Γ is a finite, distributive lattice, the **output lattice**,
- ▶ $q_0 \in Q$ is the **initial state** and
- ▶ $\delta : Q \times \Sigma \rightarrow B^+(\Gamma \times Q)$ is the **transition function**

Supporting alternating finite-state machines

Definition (Alternating Mealy Machine)

A **alternating Mealy machine** is a tuple $\mathcal{M} = (Q, \Sigma, \Gamma, q_0, \delta)$ where

- ▶ Q is a finite set of **states**,
- ▶ Σ is the **input alphabet**,
- ▶ Γ is a finite, distributive lattice, the **output lattice**,
- ▶ $q_0 \in Q$ is the **initial state** and
- ▶ $\delta : Q \times \Sigma \rightarrow B^+(\Gamma \times Q)$ is the **transition function**

Convention

Understand $\delta : Q \times \Sigma \rightarrow B^+(\Gamma \times Q)$ as a function $\delta : Q \times \Sigma \rightarrow \Gamma \times B^+(Q)$

Supporting alternating finite-state machines

Definition (Run of an Alternating Mealy Machine)

A **run** of an alternating Mealy machine $\mathcal{M} = (Q, \Sigma, \Gamma, q_0, \delta)$ on a finite word $u = a_0 \dots a_{n-1} \in \Sigma^+$ is a sequence $t_0 \xrightarrow{(a_0, b_0)} t_1 \xrightarrow{(a_1, b_1)} \dots t_{n-1} \xrightarrow{(a_{n-1}, b_{n-1})} t_n$ such that

- ▶ $t_0 = q_0$ and
- ▶ $(t_i, b_{i-1}) = \hat{\delta}(t_{i-1}, a_{i-1})$

where $\hat{\delta}$ is inductively defined as follows

- ▶ $\hat{\delta}(q, a) = \delta(q, a)$,
- ▶ $\hat{\delta}(q \vee q', a) = (\hat{\delta}(q, a)|_1 \sqcup \hat{\delta}(q', a)|_1, \hat{\delta}(q, a)|_2 \vee \hat{\delta}(q', a)|_2)$, and
- ▶ $\hat{\delta}(q \wedge q', a) = (\hat{\delta}(q, a)|_1 \sqcap \hat{\delta}(q', a)|_1, \hat{\delta}(q, a)|_2 \wedge \hat{\delta}(q', a)|_2)$

The **output** of the run is b_{n-1} .

Transition function of an alternating Mealy machine

Transition function $\delta_4^a : Q \times \Sigma \rightarrow B^+(\Gamma \times Q)$

$$\delta_4^a(\text{true}, a) = (\top, \text{true})$$

$$\delta_4^a(\text{false}, a) = (\perp, \text{false})$$

$$\delta_4^a(p, a) = (p \in a, [p \in a])$$

$$\delta_4^a(\varphi \vee \psi, a) = \delta_4^a(\varphi, a) \vee \delta_4^a(\psi, a)$$

$$\delta_4^a(\varphi \wedge \psi, a) = \delta_4^a(\varphi, a) \wedge \delta_4^a(\psi, a)$$

$$\begin{aligned} \delta_4^a(\varphi U \psi, a) &= \delta_4^a(\psi \vee (\varphi \wedge X(\varphi U \psi)), a) \\ &= \delta_4^a(\psi, a) \vee (\delta_4^a(\varphi, a) \wedge (\varphi U \psi)) \end{aligned}$$

$$\begin{aligned} \delta_4^a(\varphi R \psi, a) &= \delta_4^a(\psi \wedge (\varphi \vee \bar{X}(\varphi R \psi)), a) \\ &= \delta_4^a(\psi, a) \wedge (\delta_4^a(\varphi, a) \vee (\varphi R \psi)) \end{aligned}$$

Motivating Example

jUnit^{RV} – Idea

Using jUnit^{RV}

Fusing model checking and runtime verification

LTL with a predictive semantics

Recall anticipatory LTL semantics

The truth value of a LTL_3 formula φ wrt. u , denoted by $[u \models \varphi]$, is an element of \mathbb{B}_3 defined by

$$[u \models \varphi] = \begin{cases} \top & \text{if } \forall \sigma \in \Sigma^\omega : u\sigma \models \varphi \\ \perp & \text{if } \forall \sigma \in \Sigma^\omega : u\sigma \not\models \varphi \\ ? & \text{otherwise.} \end{cases}$$

Assumptions about environment

Definition (Semantics of LTL with Assumptions)

Let $\hat{\mathcal{P}}$ be an assumption on possible runs of the underlying system. Let $u \in \Sigma^*$ denote a finite trace. The *truth value* of u and an LTL₃ formula φ wrt. $\hat{\mathcal{P}}$, denoted by $[u \models_{\hat{\mathcal{P}}} \varphi]$, is an element of $\mathbb{B}_3 \uplus \{i\}$ and defined as follows:

$$[u \models_{\hat{\mathcal{P}}} \varphi] = \begin{cases} i & u \notin_{\omega} \hat{\mathcal{P}}, \text{ else,} \\ \top & \text{if } \forall \sigma \in \Sigma^{\omega} \text{ with } u\sigma \in \hat{\mathcal{P}} : u\sigma \models \varphi \\ \perp & \text{if } \forall \sigma \in \Sigma^{\omega} \text{ with } u\sigma \in \hat{\mathcal{P}} : u\sigma \not\models \varphi \\ ? & \text{else} \end{cases}$$

Assuming program is known, applied to the empty word

Empty word ϵ

$$[\epsilon \models \varphi]_{\mathcal{P}} = \top$$

iff $\forall \sigma \in \Sigma^\omega$ with $\epsilon\sigma \in \mathcal{P} : \epsilon\sigma \models \varphi$

iff $\mathcal{L}(\mathcal{P}) \models \varphi$

RV more difficult than MC?

Then runtime verification implicitly answers model checking

Abstraction

An **over-abstraction** or **over-approximation** of a program \mathcal{P} is a program $\hat{\mathcal{P}}$ such that $\mathcal{L}(\mathcal{P}) \subseteq \mathcal{L}(\hat{\mathcal{P}}) \subseteq \Sigma^\omega$.

Predictive Semantics

Definition (Predictive semantics of LTL)

Let \mathcal{P} be a program and let $\hat{\mathcal{P}}$ be an over-approximation of \mathcal{P} . Let $u \in \Sigma^*$ denote a finite trace. The *truth value* of u and an LTL_3 formula φ wrt. $\hat{\mathcal{P}}$, denoted by $[u \models_{\hat{\mathcal{P}}} \varphi]$, is an element of \mathbb{B}_3 and defined as follows:

$$[u \models_{\hat{\mathcal{P}}} \varphi] = \begin{cases} i & u \notin_{\omega} \hat{\mathcal{P}}, \text{ else,} \\ \top & \text{if } \forall \sigma \in \Sigma^{\omega} \text{ with } u\sigma \in \hat{\mathcal{P}} : u\sigma \models \varphi \\ \perp & \text{if } \forall \sigma \in \Sigma^{\omega} \text{ with } u\sigma \in \hat{\mathcal{P}} : u\sigma \not\models \varphi \\ ? & \text{else} \end{cases}$$

We write $\text{LTL}_{\mathcal{P}}$ whenever we consider LTL formulas with a predictive semantics.

Properties of Predictive Semantics

Let $\hat{\mathcal{P}}$ be an over-approximation of a program \mathcal{P} over Σ , $u \in \Sigma^*$, and $\varphi \in \text{LTL}$.

- ▶ Model checking is more precise than RV with the predictive semantics:

$$\mathcal{P} \models \varphi \text{ implies } [u \models_{\hat{\mathcal{P}}} \varphi] \in \{\top, ?\}$$

- ▶ RV has no false negatives: $[u \models_{\hat{\mathcal{P}}} \varphi] = \perp$ implies $\mathcal{P} \not\models \varphi$
- ▶ The predictive semantics of an LTL formula is more precise than LTL_3 :

$$[u \models \varphi] = \top \quad \text{implies} \quad [u \models_{\hat{\mathcal{P}}} \varphi] = \top$$

$$[u \models \varphi] = \perp \quad \text{implies} \quad [u \models_{\hat{\mathcal{P}}} \varphi] = \perp$$

The reverse directions are in general not true.

Monitor generation

The procedure for getting $[u \models_{\hat{P}} \varphi]$ for a given φ and over-approximation \hat{P}

RV-LTL

LTL with a Predictive Semantics

LTL wrap-up

Extensions

Monitoring Systems/Logging

Steering

RV frameworks

jUnit^{RV} – Testing Temporal Properties

Motivating Example

jUnit^{RV} – Idea

Example Application

- ▶ Some application for data entry
- ▶ Connects to a server
- ▶ Data can be read, modified and committed

Example Application

- ▶ Frontend handles GUI
- ▶ Backend handles communication to the server
- ▶ Frontend and backend communicate via the following interface:

Example

```
public interface DataService {  
    void connect(String userID) throws UnknownUserException;  
    void disconnect();  
    Data readData(String field);  
    void modifyData(String field, Data data);  
    void commit() throws CommitException;  
}
```

A “simple” Test

- ▶ Frontend has to use backend *correctly*
- ▶ Data has to be committed before disconnecting

Example

@Test

```
public void test1() {  
    DataService service = new MyDataService("http://myserver.net");  
    MyDataClient client = new MyDataClient(service);  
  
    client.authenticate("daniel");  
    client.addPatient("Mr. Smith");  
    client.switchToUser("ruth");  
    assertTrue(service.debug_committed()); // switching means logout  
    client.getPatientFile("miller-2143-1");  
    client.setPhone("miller-2143-1", "012345678");  
    client.exit();  
    assertTrue(service.debug_committed());  
}
```

Observations

- ▶ Test inputs are *interleaved* with assertions
- ▶ Requires internal knowledge about the class under scrutiny
- ▶ Requires refactoring of interfaces between components
- ▶ Components might need additional logic to track temporal properties
- ▶ Production code is polluted by test code
- ▶ Program logic for temporal properties can be complicated

⇒ Classical unit testing is not suitable to assure temporal properties on internal interfaces

jUnit^{RV} – Idea

Using jUnit^{RV}

Events and Propositions

- ▶ Formal runs consist of discrete steps in time
- ▶ When does a program perform a step?
- ▶ Explicitly specify events triggering time steps
- ▶ Only one event occurs at a point of time
- ▶ Propositions may be evaluated in the current state

Events and Propositions

Example (Specifying Events)

```
String dataService = "myPackage.DataService";  
private static Event modify = called(dataService, "modify");  
private static Event committed = returned(dataService, "commit");  
private static Event disconnect = called(dataService, "disconnect");
```

Example (Specifying Propositions)

```
private static Proposition auth  
    = new Proposition(eq(invoke($this, "getStatus"), AUTH);
```

Temporal Assertion

- ▶ LTL is used to specify temporal properties
- ▶ Generated monitors only observe the specified events
- ▶ $G(\text{modify} \rightarrow \neg \text{disconnect} U \text{committed})$

Example (Specifying Monitors)

```
private static Monitor commitBeforeDisconnect = new FLTL4Monitor(  
    Always (implies (  
        modify,  
        Until (not(disconnect), committed)  
    )  
));
```

Testcase

Example

```
@Test  
@Monitors({"commitBeforeDisconnect"})  
public void test1() {  
    DataService service = new MyDataService("http://myserver.net");  
    MyDataClient client = new MyDataClient(service);  
  
    client.authenticate("daniel");  
    client.addPatient("Mr. Smith");  
    client.switchToUser("ruth");  
    client.getPatientFile("miller-2143-1");  
    client.setPhone("miller-2143-1", "012345678");  
    client.exit();  
}
```

The Complete Picture

```
@RunWith(RVRunner.class)
public class MyDataClientTest {

    private static final String dataServiceQname = "junitrvexamples.DataService";
    private static Event modify = called(dataServiceQname, "modifyData");
    private static Event committed = returned(dataServiceQname, "commit");
    private static Event disconnect = invoke(dataServiceQname, "disconnect");

    // create a monitor for LTL4 property G(modify -> !close U commit)
    private static Monitor commitBeforeClose = new FLTL4Monitor(
        Always (
            implies(
                modify,
                Until (not(disconnect), committed)));

    @Test
    @Monitors({"commitBeforeClose", "authWhenModify"})
    public void test1() {
        ...
    }
}
```

Motivating Example

jUnit^{RV} – Idea

Using jUnit^{RV}

Architecture

Runners and Classloaders

- ▶ jUnit uses test runners to execute tests
- ▶ jUnit provides a default implementation
- ▶ jUnit^{RV} provides `RVRunner` extending the default implementation
- ▶ jUnit^{RV} provides a custom `ClassLoader`
- ▶ Class loading by program under scrutiny is intercepted
- ▶ Bytecode is manipulated to intercept events

Features

- ▶ `jUnitRV` is provided as single class jar file that has to be made available on the Java class path
- ▶ It can easily integrated into build systems and IDEs
- ▶ It may be used to test third party components where no byte code is available
- ▶ It may be extended with custom specification formalisms
- ▶ Test failures are reported as soon as a monitor fails
- ▶ Stack traces show the exact location of the failure in the program under scrutiny

jUnit^{RV} Running in Netbeans

The screenshot shows the NetBeans IDE interface. The main editor displays the source code for `MyDataClientTest.java`. The code includes an `implies` method, a `private static` `Monitor` instance, and a `@Test` annotated `test1()` method. The `test1()` method performs several actions: creating a `MyDataService`, a `MyDataClient`, authenticating a user, adding a patient, switching to a user, getting a patient file, and setting a phone number. The IDE also shows a `Test Results` window at the bottom, indicating that 1 test passed and 2 tests failed (0.091 s). The failed tests are `test1` and `test2`, both failing due to a `Monitor` error.

```

31     implies(
32         modify,
33         until(not(close), committed));
34
35     // create a monitor for LTL4 property
36     //(modify W opened) & G(close ~ modify MJ opened)
37     private static Monitor openBeforeModify = new RLT4Monitor(
38         and(MJ(not(modify), opened),
39             G(implies(close, MJ(not(modify), opened)))));
40
41     @Test
42     @Monitors({@commBeforeClose, *openBeforeModify})
43     public void test1() {
44         DataService service = new MyDataService("http://myserver");
45         MyDataClient client = new MyDataClient(service);
46         client.authenticate("daniel");
47         client.addPatient("Mr. Smith");
48         client.switchUser("ruth");
49         client.getPatientFile("miller-2143-1");
50         client.setPhone("miller-2143-1", "012345678");
51         client.exit();
    
```

Test Results: `junbrvexamples.MyDataClientTest`

- 1 test passed, 2 tests failed (0.091 s)
- junbrvexamples.MyDataClientTest Failed
 - test1 Failed: Monitor commBeforeClose evaluated to FALSE
 - test2 Failed: Monitor commBeforeClose terminated with PPALISE

jUnitRV – Summary

- ▶ Unit testing and runtime verification are combined
- ▶ jUnit is extended by temporal assertions
- ▶ Testing temporal properties is less cumbersome
- ▶ jUnit^{RV} integrates easily in existing projects and environments

Presentation outline

Using jUnit^{RV}

Conclusion

Summary

- ▶ RV needs similar temporal logics as model checking, but adaptations for
 - ▶ finite runs
 - ▶ impartiality
 - ▶ anticipation
 - ▶ prediction
- ▶ Application `jUnitRV`

That's it!
